SUBJECT: TOXICITY TEST SPECIES SUBSTITUTION, VENTURA COUNTY MUNICIPAL SEPARATE STORM SEWER SYSTEM DISCHARGE (MS4) PERMIT (BOARD ORDER No. 09-0057; NPDES No. CAS004002)

Dear Ms. Camacho:

On October 14, 2009, the Regional Board staff received a request from the Ventura County Watershed Protection District (County) to substitute topsmelt, *Atherinops affinis*, with the inland silverside, *Menidia beryllina*, due to the unavailability of topsmelt from the supplier. After consultation with US EPA staff, Regional Board staff denied the request. On October 15, 2009, the Regional Board received an e-mail from the County, titled "Notification of toxicity exception - (species unavailable) Ventura County MS4 NPDES Permit Order No. 09-0057 (Monitoring Program)". The County's e-mail communication was submitted pursuant to requirements in subparts D.5 and D.8(b) of the Ventura County MS4 Permit's Monitoring Program (Monitoring Program), which requires an explanation of the circumstance with documentation when toxicity tests cannot be performed to comply with the requirements of this permit, and written authorization from the Regional Board Executive Officer to substitute test species.

In order to evaluate the appropriateness of substituting topsmelt, *Atherinops affinis*, with the inland silverside, *Menidia beryllina*, in toxicity testing at mass emissions stations in the future, the Regional Board requires the County to conduct comparative static renewal toxicity tests on both species as follows. During the next storm event of this permit year (2009-10) and the first storm event of next permit year (2010-11), the County shall conduct toxicity tests on both topsmelt, *Atherinops affinis*, and the inland silverside, *Menidia beryllina*, along with giant kelp, *Macrocystis pyrifera*, and the purple sea urchin, *Strongylocentrotus purpuratus*, pursuant to subpart D.8(a) of the Monitoring Program. The County shall submit the results of the comparative toxicity tests as part of its reporting requirements.

RECEIVED
NOV 5 2009
WATERSHED PROTECTION DIST.

In the event that topsmelt, *Atherinops affinis*, is unavailable for testing during future sampling events conducted under the Monitoring Program, the County shall follow the protocol set forth in subpart D.5 of the Monitoring Program. The County shall notify the Regional Board by phone and e-mail as soon as possible if a test species is unavailable. Notification shall be sent directly to me as well as Tracy Woods, Stormwater Permitting Unit, with a copy to Renee Purdy, Chief, Regional Programs Section. The County shall submit to the Regional Board documentation of species unavailability from both the County's contract lab and the contract lab's supplier at least 48 hours prior to the planned sampling event to provide adequate time for my staff to evaluate any request for species substitution. Any approval or denial of a request for species substitution must be authorized pursuant to subpart D.8(b) of the Monitoring Program.

If you have any questions, please contact me at (213) 576-6605, or Renee Purdy at (213) 576-6783.

Sincerely,

Tracy J. Egoscue,
Executive Officer

Dear Mr. Anselm:

Please find the enclosed report *Ventura County Watershed Protection District NPDES Stormwater Monitoring Program Selenastrum capricornutum Phase 1 Toxicity Identification Evaluation (TIE) for One Sample Collected in October 2010. The sample was identified as MO-MPK and was assigned the lab# VCF1010.336.* The report describes in detail the three TIE analyses that were conducted on the sample that exhibited toxicity. In addition, one 96-hour acute baseline bioassay report is included. This is the initial bioassay test that was conducted on the sample received; the results of which were used to determine whether or not to proceed with TIE manipulations.

Please do not hesitate to contact us if you have any questions regarding this project.

Yours very truly,

Scott Johnson

APPENDIX 1 - RESULTS OF INITIAL BASELINE BIOASSAY TEST

SUMMARY

During the month of October 2010, one sample was received in this laboratory from the Ventura County Watershed Protection District for the analysis of chronic toxicity of the green algae, *Selenastrum capricornutum*. Initial toxicity tests were used to determine if further evaluations were necessary. The sample demonstrated sufficient toxicity to proceed with Phase 1 Toxicity Identification Evaluations (TIE's). Final analysis of results compared 96-hour IC50's from manipulated samples to that of an unaltered effluent baseline. The following conclusions were drawn from the TIE evaluations:

Based on the results of all sample manipulations treatment with PBO additions to the sample did reduce toxicity more significantly than other treatments. Therefore, metabolically-activated organophosphate compounds are suspect. C18 extraction and sodium thiosulfate additions did reduce toxicity to a lesser degree therefore non-polar organic compounds and chemicals used in disinfection and chlorination also are indicated as sources of toxicity.

INTRODUCTION

The EPA Phase 1 TIE procedures were designed for the characterization of municipal and industrial effluents and stormwater runoff. After conducting an initial bioassay to determine the level of toxicity in a sample, various manipulations are performed to identify which group of compounds appear to be causing the toxicity. The toxicant groups targeted are volatile or oxidizable compounds, particulate-bound toxins, cationic metals, non-polar organics, and organophosphates. The following manipulations are typically performed:

C_{18}-Solid Phase Extraction uses a sorbent column to evaluate the contribution to sample toxicity of non-polar organic compounds and certain metals or metal chelates. Non-polar compounds are trapped in the column through solubility and polarity interactions with the C_{18}.

Piperonyl Butoxide (PBO) blocks the action of metabolically-activated organophosphate compounds. The addition of PBO therefore reduces toxicity of samples containing organophosphates.

Sodium Thiosulfate neutralizes chemicals used in disinfection, chlorination, and some electrophilic organic chemicals.

At the Phase 1 level of testing, relatively small sample sizes and limited replications make statistical inferences difficult. Often 95% confidence limits on IC50 values are not calculable, and thus the statistical significance of substantial changes in post-manipulation toxicity may not be possible to establish. This is especially true in cases of samples with low to moderate initial 96-hour toxicity (i.e. IC50's greater than 50%). Therefore, considerable latitude must be given when interpreting the results of Phase 1 TIE's.

MATERIALS AND METHODS

The following sample was received in this laboratory under chain-of-custody procedures on the following dates. The sampling containers were new five-gallon poly buckets with sealed lids. The sample was identified as:

MO-MPK VCF1010.336

Chronic growth toxicity tests were used throughout the TIE characterizations (the toxicity pre-screen assessed 96-hour growth data from a 96-hour chronic toxicity test). Initial testing was performed in accordance with *Short-Term Methods for Estimating the Chronic Toxicity of Effluents and Receiving Waters to Freshwater Organisms EPA-821-R-02-013*. If observed growth in the pre-screen exhibited a TUc of >1.00, the TIE process was initiated. An initial 96 hour test of chronic toxicity was set up on Day 1. Sample aliquots were manipulated the day following the end of the baseline test and TIE exposure concentrations, based on growth observed after 96 hours in the initial test, were set up. Final analyses compared *Selenastrum capricornutum* 96-hour IC50's of each manipulated aliquot to that of the unaltered sample.

Procedures of each chemical or physical manipulation followed those described in *Methods for Aquatic Toxicity Identification Evaluations, Phase 1 Toxicity Characterization Procedures* (Second Edition), EPA/600/6-91/003.

Solid phase extraction of the sample utilized a C_{18} column. Two post-column aliquots were subjected to bioassay testing in each treatment. The first aliquot was taken after 25 ml of sample had passed the column to ensure that no dilution water is left in the system. To assess the extent of column overloading and possible toxicant breakthrough, a second aliquot was taken after 150 ml of sample had passed.

Piperonyl butoxide stock solution was added to each 10 ml test aliquot at five rates: 25 ppb, 50 ppb, 100 ppb, 250 ppb and 500 ppb. The stock solution concentration was based on EPA recommendations.

Sodium thiosulfate stock was added to each 10 ml aliquot at five rates: 1.0 ml, 0.8 ml, 0.6 ml, 0.4 ml, and 0.2 ml. The stock solution concentration was based on sodium thiosulfate 96 hour IC50's for *Selenastrum capricornutum*.

Selenastrum capricornutum used in testing is cultured in-house. The algae is cultured in EPA reconstituted freshwater. Initial and baseline tests were conducted with duplicate samples. All subsequent testing of manipulated samples were conducted in duplicate. The test temperature was 25 $\pm$ 1 deg C in an environmental chamber with constant light. Toxicity tests were 96 hours in duration. Growth was the endpoint evaluated for the green algae. Sample concentration ranges for toxicity tests were dependent upon the sample's initial 96-hour LC50. The 96-hour IC50 was 35.9%, therefore a concentration series of ½X, 1X, 2X and 4X the IC50 were used (18, 36, 72, and 100%'s for this sample). For Sodium Thiosulfate, and PBO manipulations, the highest sample concentration of 100% was used.

For TIE comparisons, sample toxicity is expressed in Toxicity Units (TU) which increase directly with toxicity:

$$TU = \frac{100}{IC50}$$

Calculation of IC50s was performed by the linear interpolation method (EPA Bootstrap; 120 iterations).

RESULTS/CONCLUSIONS

SAMPLE MO-MPK

MO-MPK was collected on 30 October 2010, and was received at 0825 hours on 30 October 2010. The sample was assigned laboratory identification number VCF1010.336. A 4 day chronic test was set up on October 30. At the end of 4 days the sample exhibited toxicity (TUc >1.00). TIE procedures were initiated. The 96-hour baseline test yielded an IC50 of 35.9% was observed. Based on this data the dilution series for the TIE test was assigned at 18, 36, 72, & 100%'s. Bioassay results obtained from the manipulated aliquots were compared to the baseline test values and are summarized below:

* Solid phase extraction with C_{18} did reduce toxicity. Therefore, non-polar organic compounds are suspect.

* Treatment of the sample with PBO did reduce the toxicity. Therefore, metabolically-activated organophosphate compounds are suspected toxicants in the sample.

* Additions of sodium thiosulfate did reduce toxicity therefore chemicals used in disinfection, chlorination and some electrophilic organic compounds are suspect.
